"Interpreting and Using Regression" is a practical introductory guide that explains regression analysis and how to interpret the results. The text is written in plain English. Achen offers easy-to-understand examples and analogies to illustrate the concepts and procedures in this short (but unfortunately expensive) book.

In the tutorial on prediction we used the regression line to predict values of y for values of x. That is, the regression line is a way of using your data to predict what an average y value should be for a given value of x.

Interpreting Regression - University of Washington

In this chapter we discuss regression models. The basic concept is that we forecast the time series of interest $\{y_t\}$ assuming that it has a linear relationship with other time series $\{x_t\}$. For example, we might wish to forecast monthly sales $\{y_t\}$ using total advertising spend $\{x_t\}$ as a predictor.

Let's take a look at how to interpret each regression coefficient. Interpreting the Intercept. The intercept term in a regression table tells us the average expected value for the response variable when all of the predictor variables are equal to zero. In this example, the regression coefficient for the intercept is equal to 48.56.

To formally test whether a linear trend occurs, run a time series regression with a time trend as the independent variable, which you can set up like so: In this example, the dependent variable is the price of Microsoft stock, and the independent variable is time (measured in months). The next figure shows the results of this regression analysis.

Regression analysis that uses polynomials to model curvature can make interpreting the results trickier. Unlike a linear relationship, the effect of the independent variable changes based on its value. Looking at the coefficients won't make the picture any clearer. Instead, graph the data to truly understand the relationship.

Regression is a parametric technique used to predict continuous (dependent) variable given a set of independent variables. It is parametric in nature because it makes certain assumptions (discussed next) based on the data set. If the data set follows those assumptions, regression gives incredible results.

When using regression models for time series data, we need to distinguish between the different types of forecasts that can be produced, depending on what is assumed to be known when the forecasts are computed. Ex-ante forecasts are those that are made using only the information that is available in advance.

Time series regression is a statistical method for predicting a future response based on the response history (known as autoregressive dynamics) and the transfer of dynamics from relevant predictors. Time series regression can help you understand and predict the behavior of dynamic systems from experimental or observational data.
